

Software maintenance and Evolution

Prof. Romain Robbes

Outline

About this class

A brief history of Software Engineering

Essential and accidental difficulties in Software Engineering

Maintenance & evolution: facts and figures

The software change process

Change initiation

About this class

Course Format

Frontal lectures

~~Monday 14:00 – 16:00~~

~~Wednesday 14:00 – 16:00~~

Labs

~~Monday 16:00 – 18:00~~

Office hours

Course Format

Frontal lectures

~~Wednesday 14:00 – 16:00~~

Thursday, 12:00–14:00

Labs

~~Monday 14:00 – 18:00~~

Tuesday, 08:00–12:00
(Today we end at 10:00)

Office hours

Topics of this class: How to evolve software systems

Basic techniques

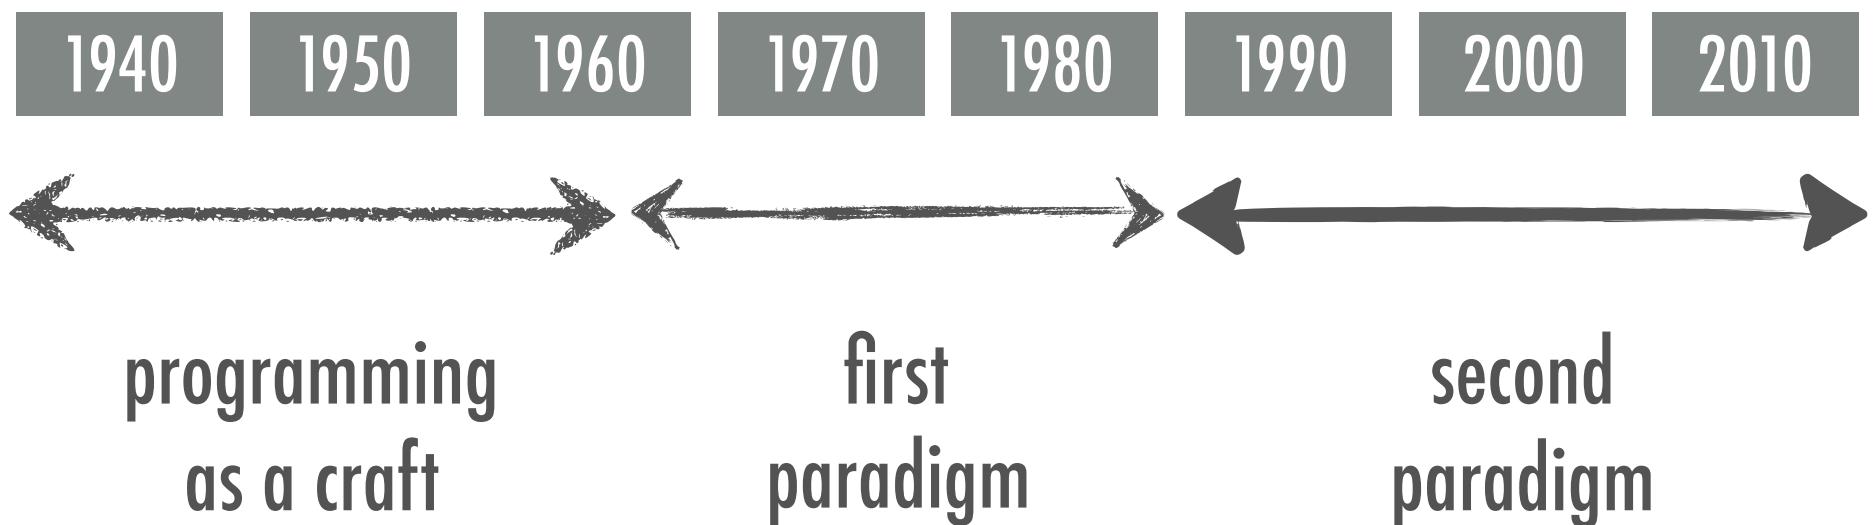

- Concept location
- Impact analysis
- Change propagation
- Refactoring
- Verification

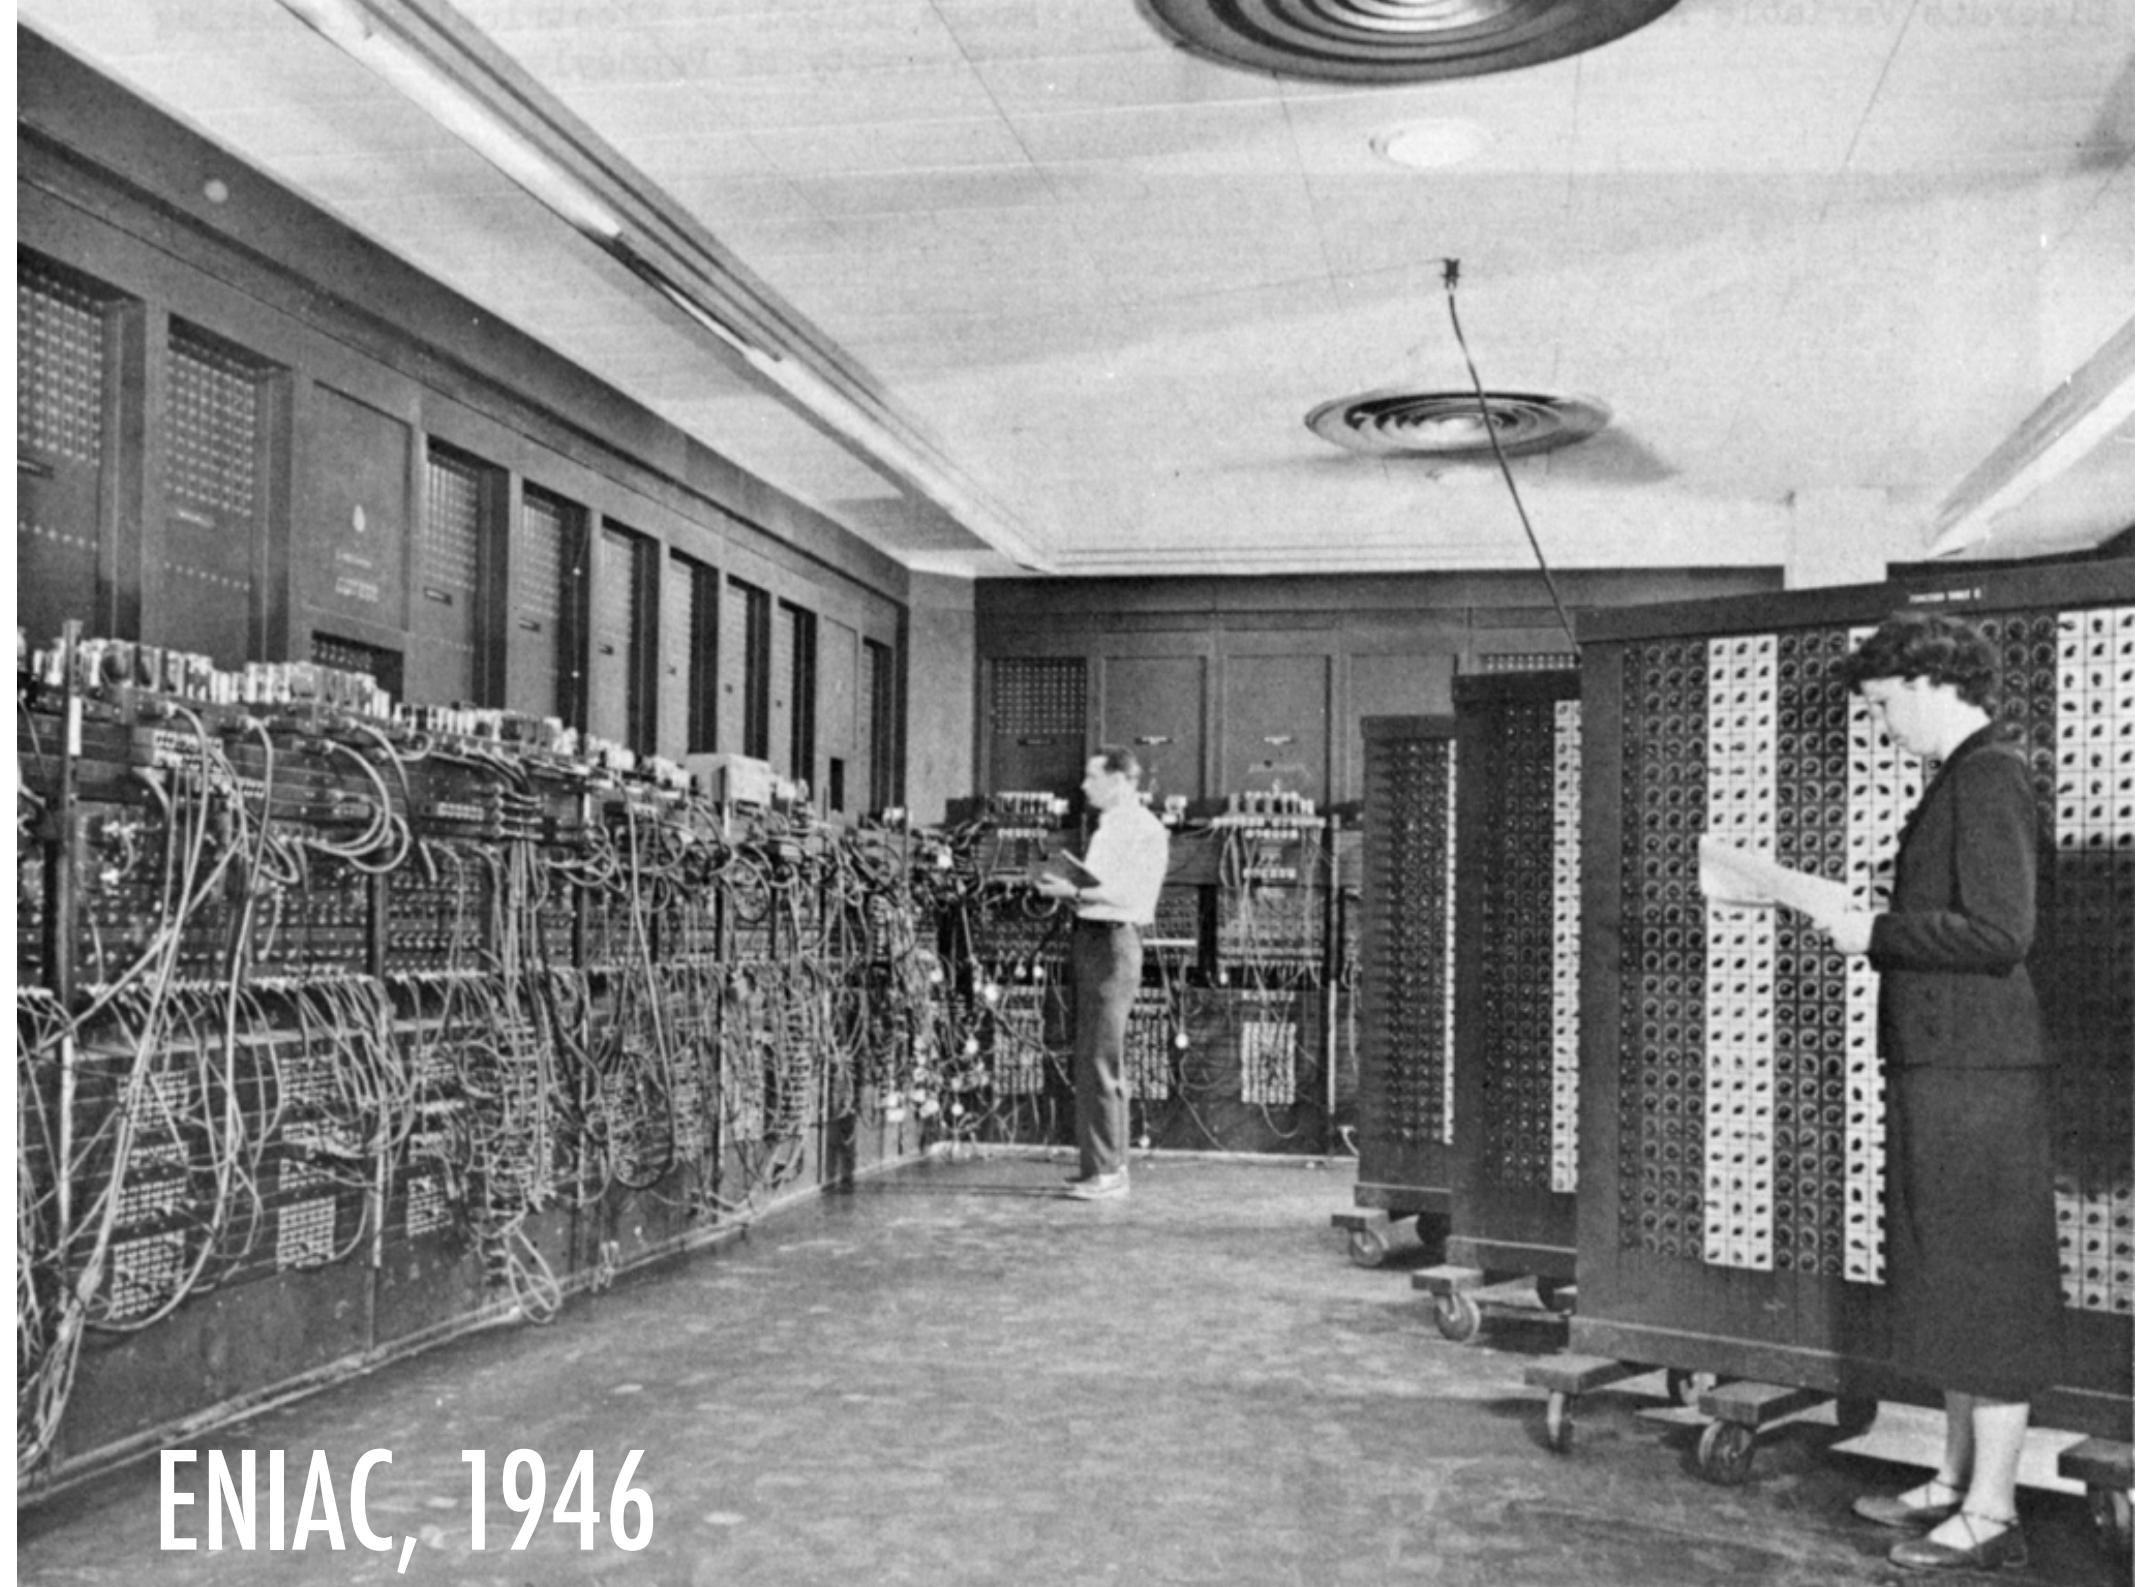

Advanced techniques

- Mining Software Repositories
- Software Metrics
- Text Analysis
- Defect Prediction
- Search-based Techniques

A brief history of software engineering (Or, why we need all this)

Software engineering timeline

First actual case of bug being found.

1700 closed down .

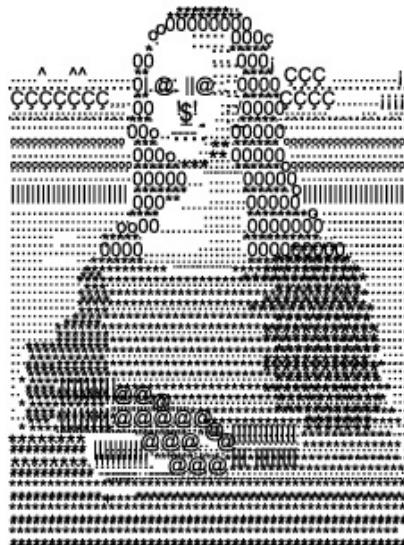

When programs were “simple”

Programs: differential equations, ballistics, ...

No “programmers”: physicists, mathematicians

Hardware cost dominates: ENIAC cost 6,000,000 \$ (U.S.)

Programming is an art

Programming is an art ... until the 60's

IBM's OS/360 proves that this approach has limits

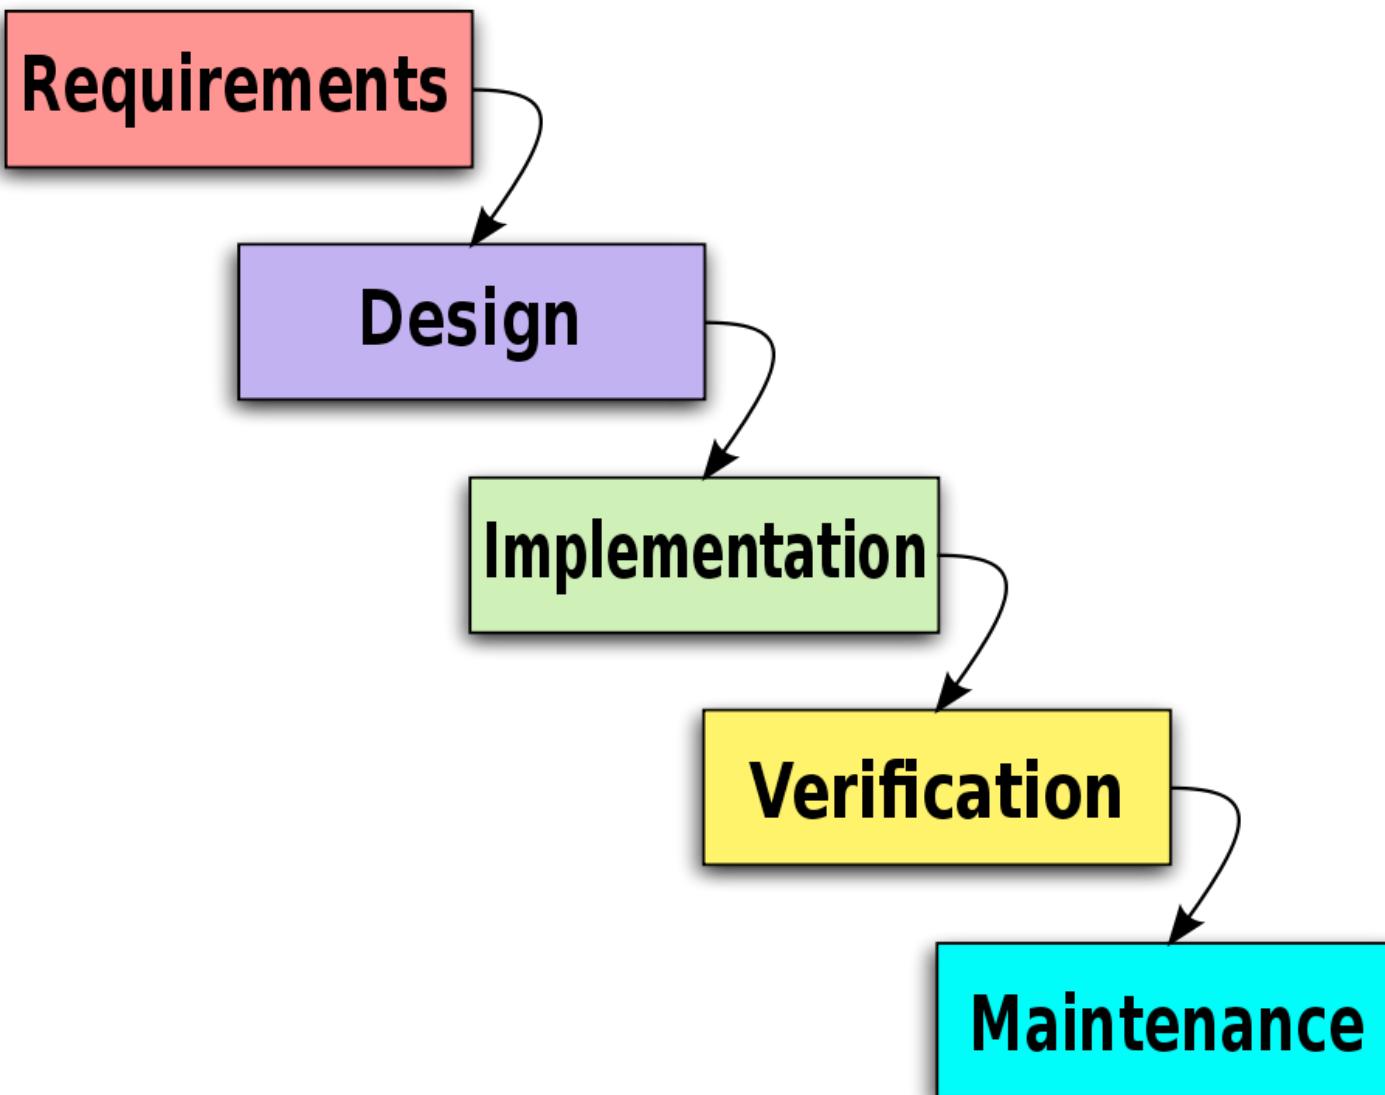

Discovery: adding people to a late project slows it down!

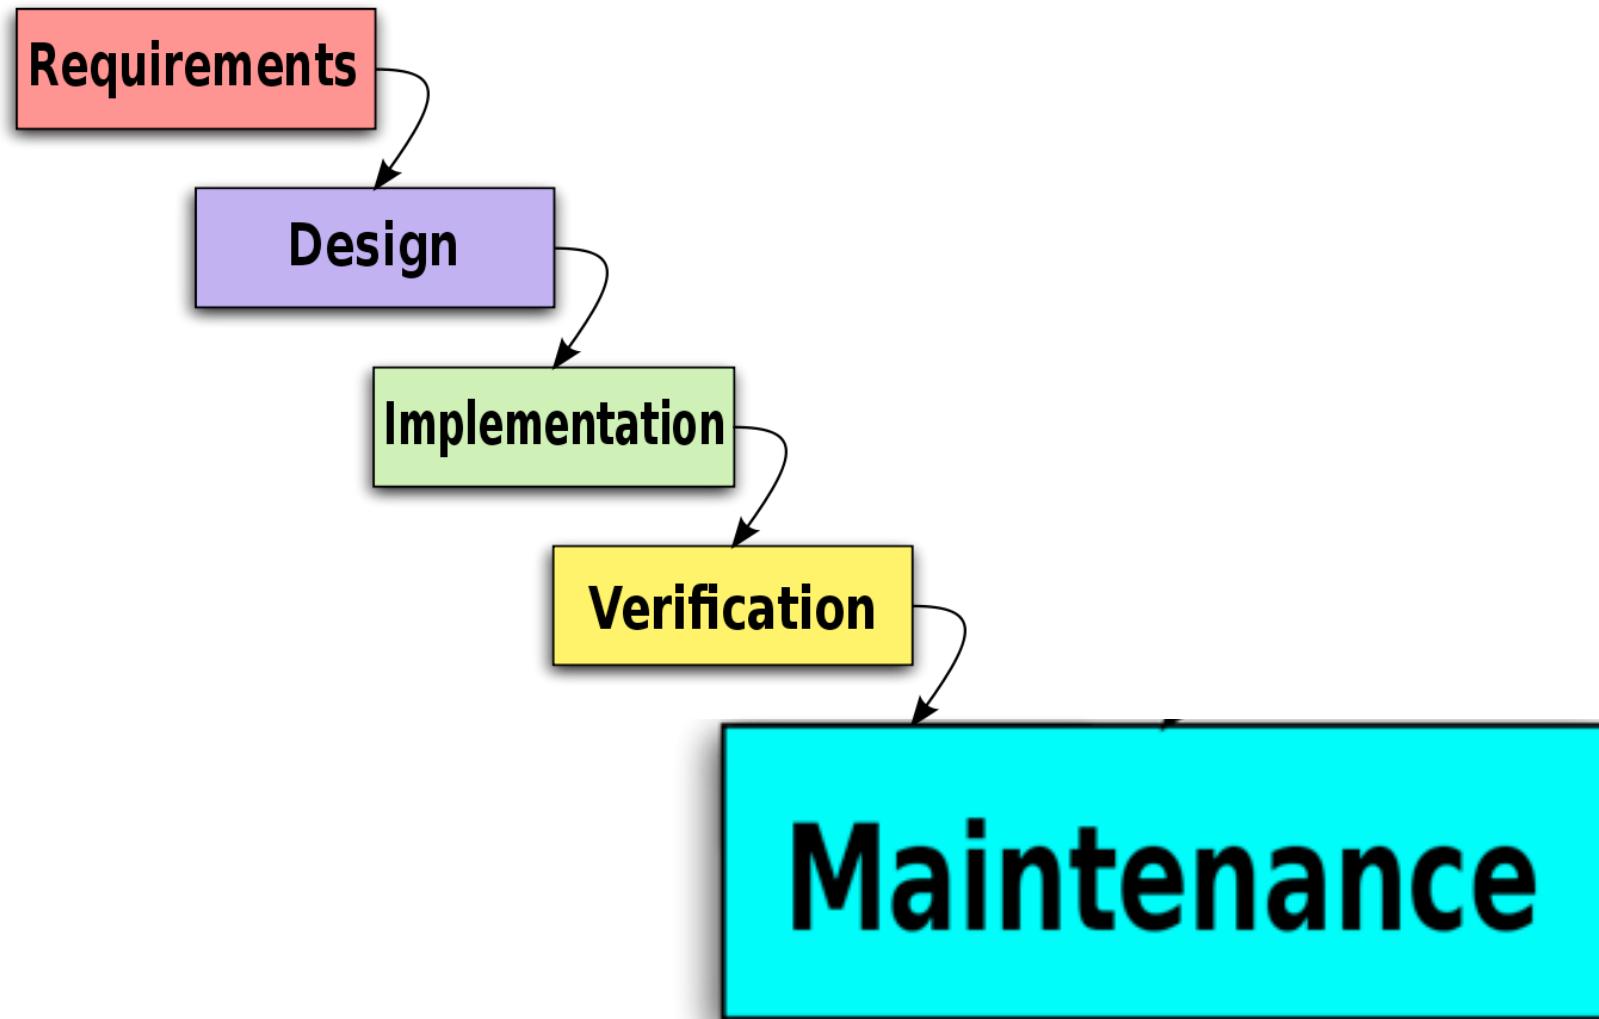

First software engineering conferences, 1968 and 1969

The first standards activities and processes emerge, e.g. waterfall

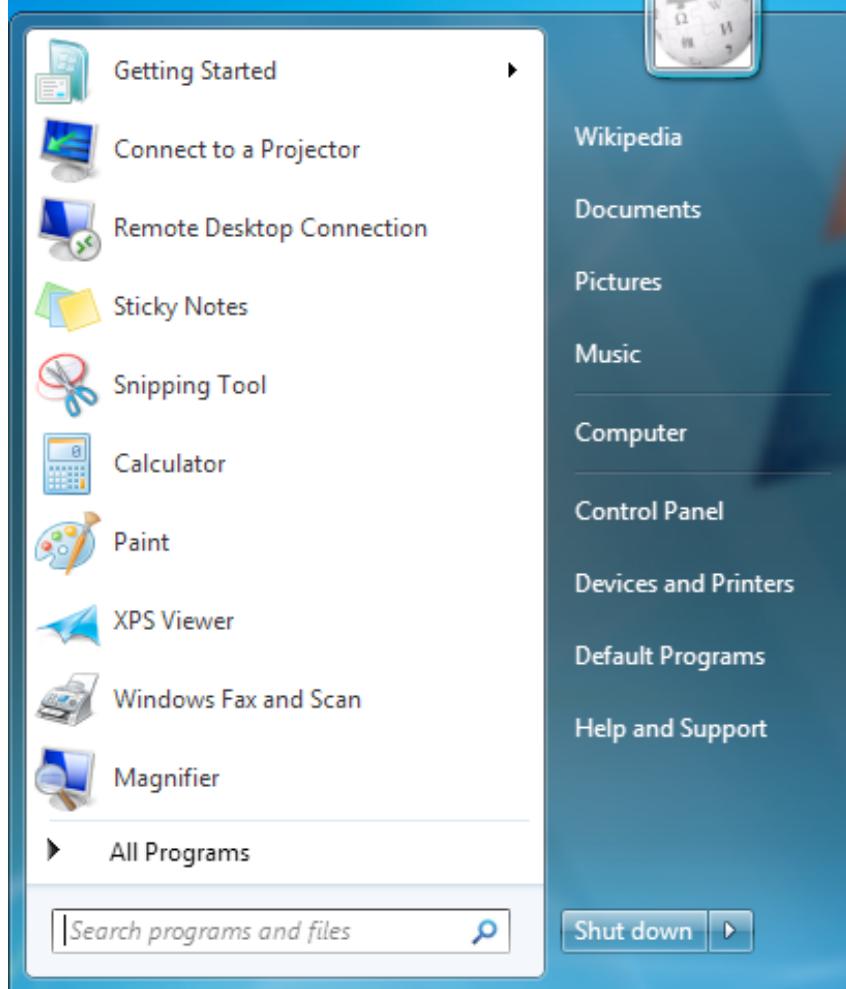

During the 80's and 90's, people realize that software systems live very long!

Windows is 25 years old

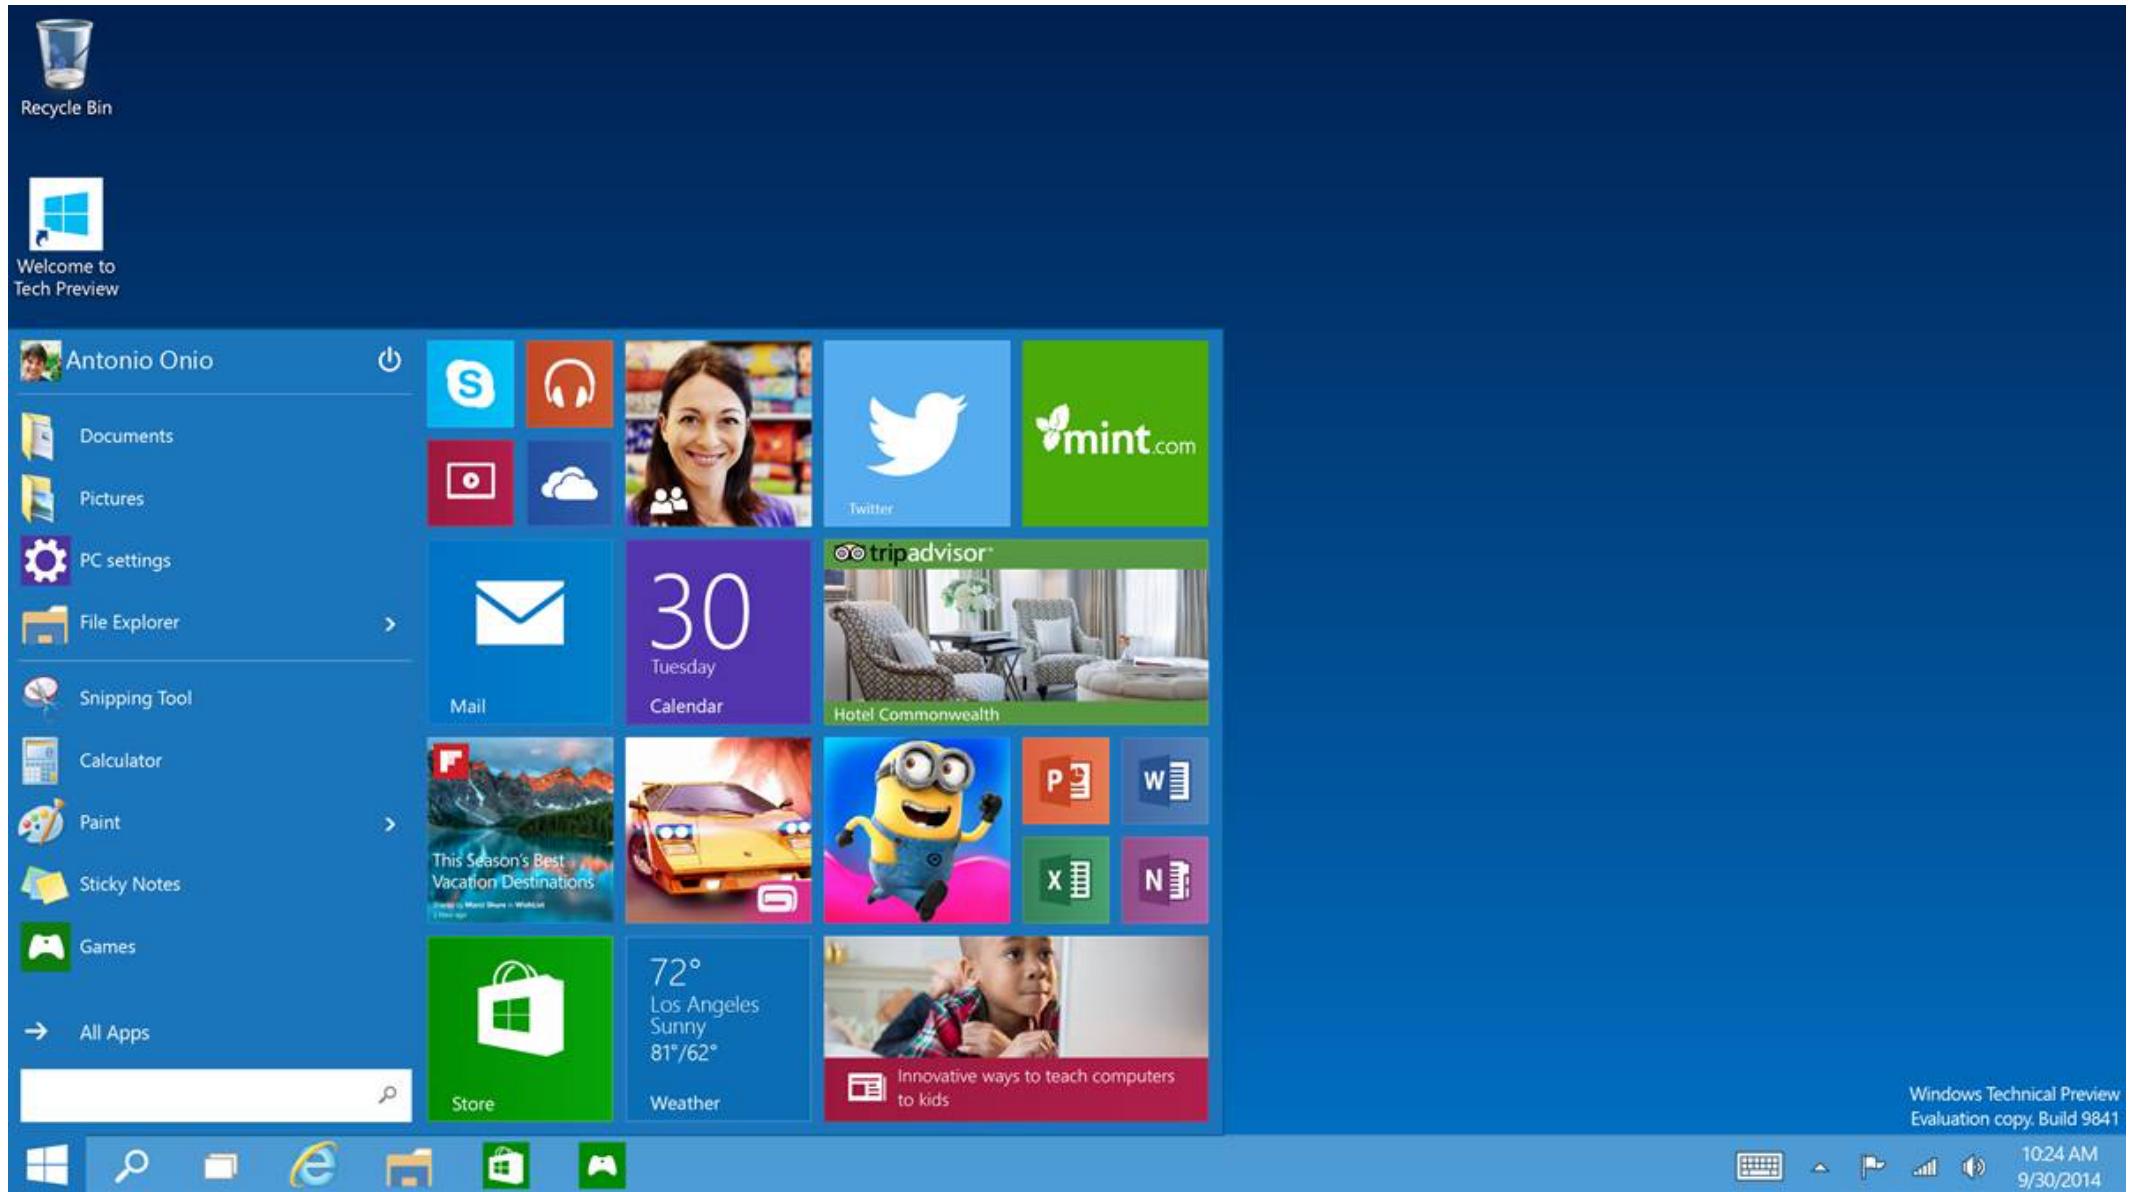

Recycle Bin

Scratch that, make it 30

The **difficulties** of software development

What do **you** think?

Essential vs. accidental difficulties

Essential difficulties:
properties specific to software that are always present.

Accidental difficulties:
properties that may vary from one system to another.

The 5 essential difficulties of software

Complexity

Invisibility

Changeability

Conformity

Discontinuity

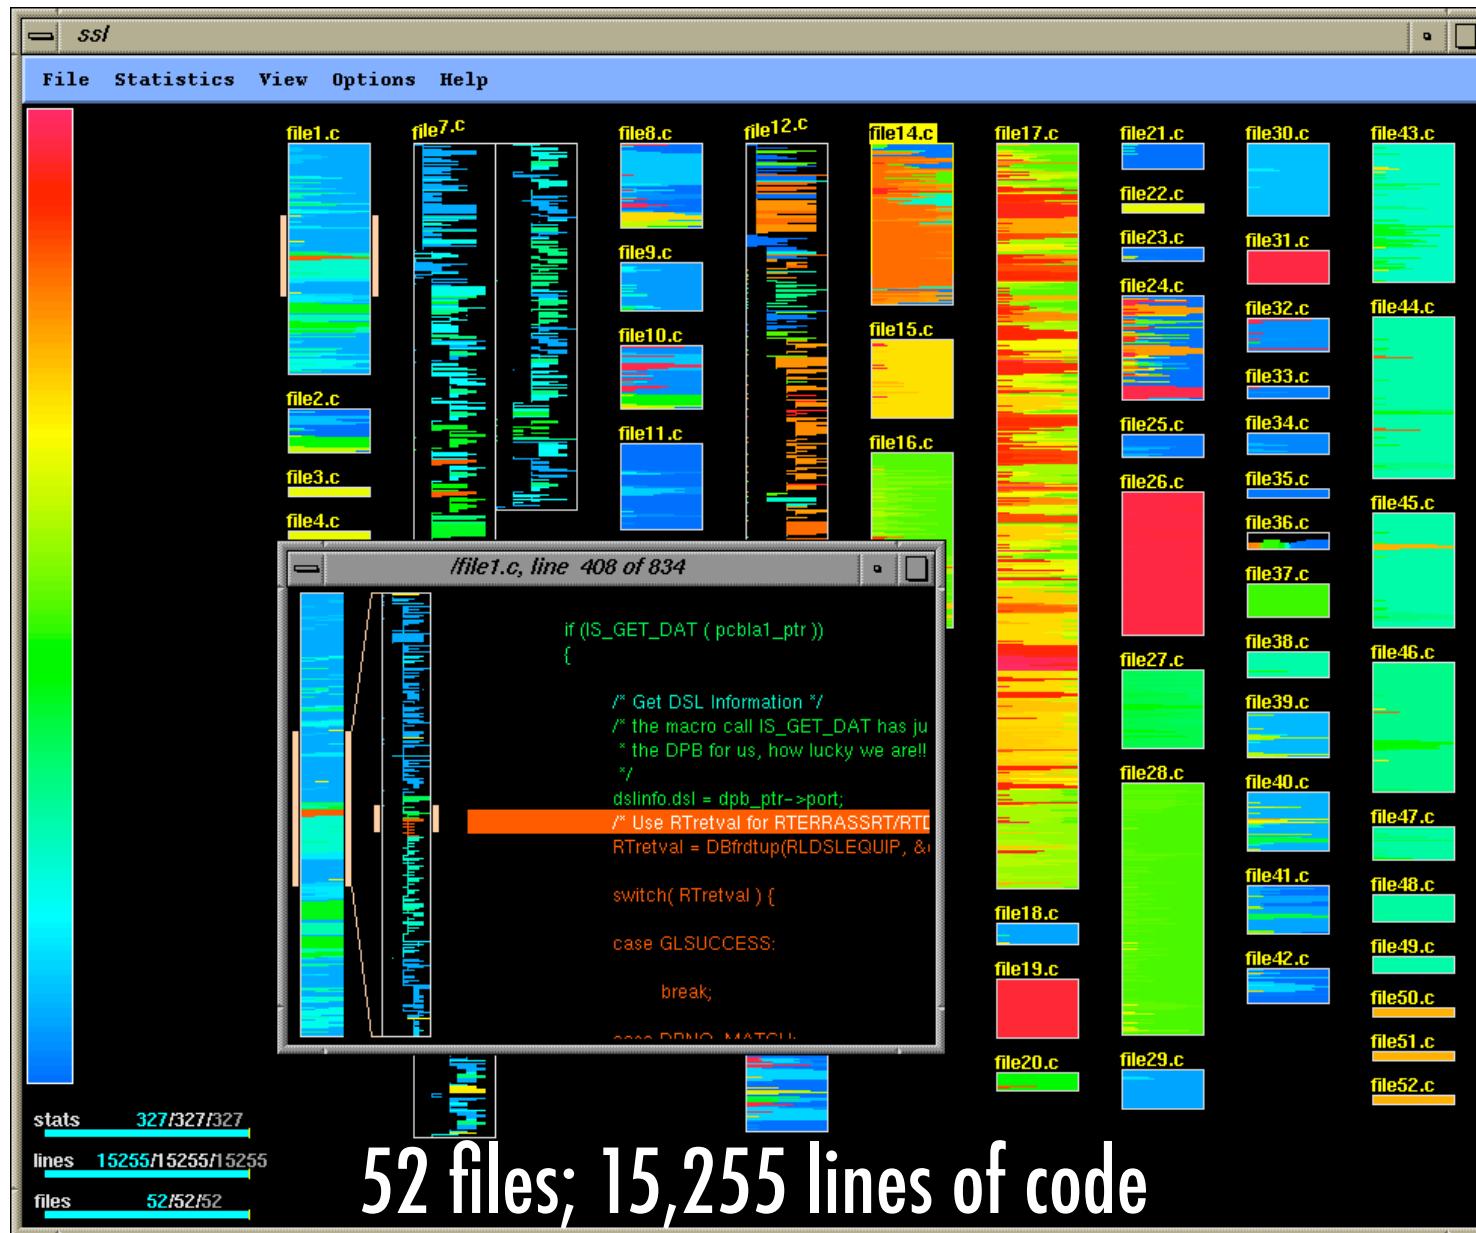

Software is complex

```
#include <stdio.h>
#include <stdlib.h>

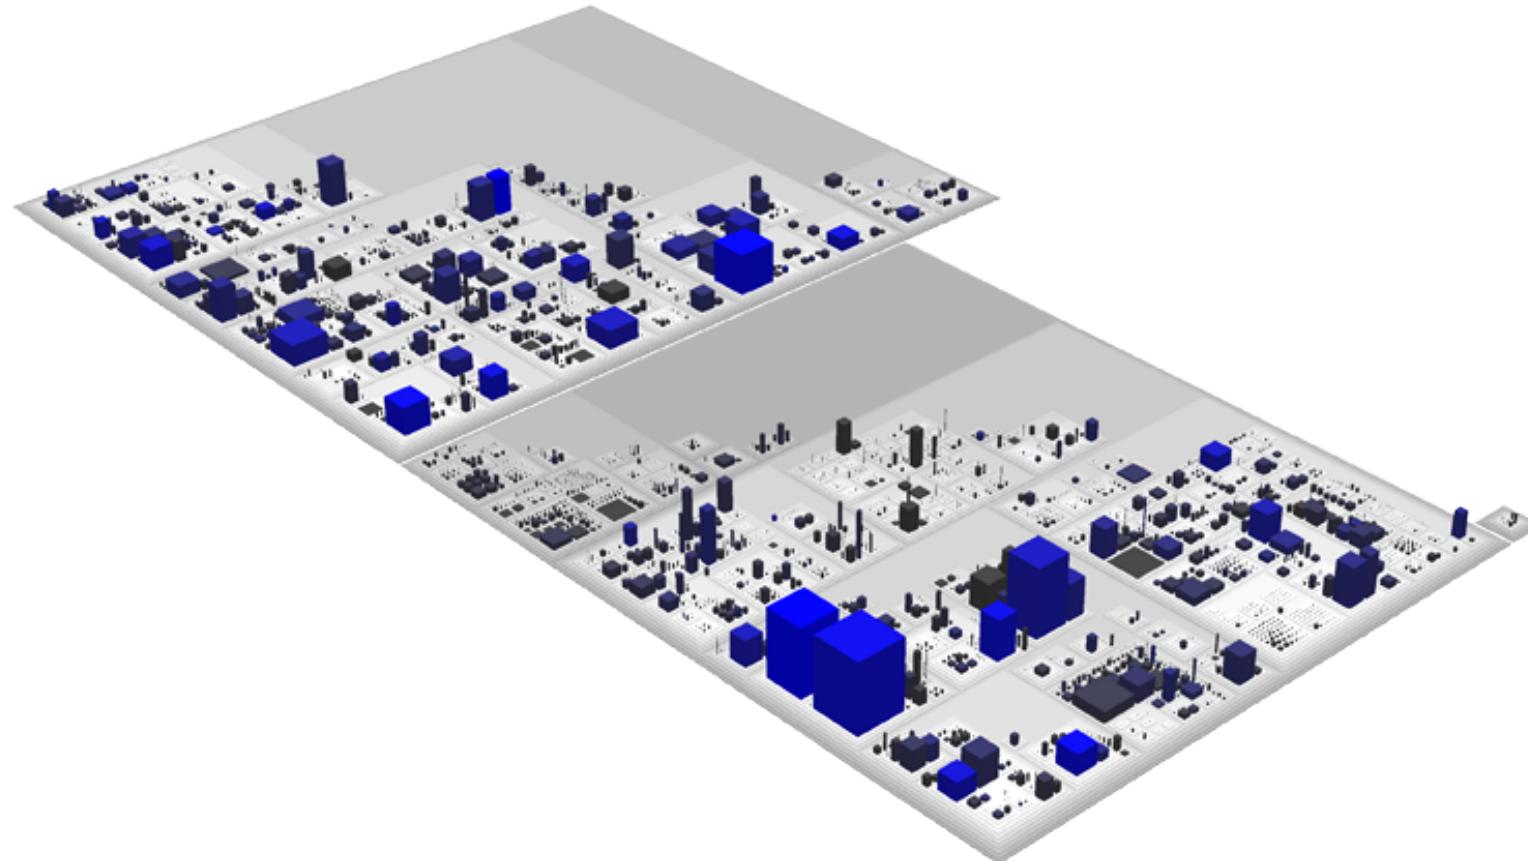

main( )
{
    int i;
    for ( i=0; i<10; i=i+1 );
        printf("i is %d\n",i);
}
```

main.c: 1 file, 9 lines of code

Now consider the following code ...

Now consider the following code ...

Azureus: 4,656 classes; 454,387 lines of code

Now consider the following code ...

Windows Vista: 50,000,000+ lines of code

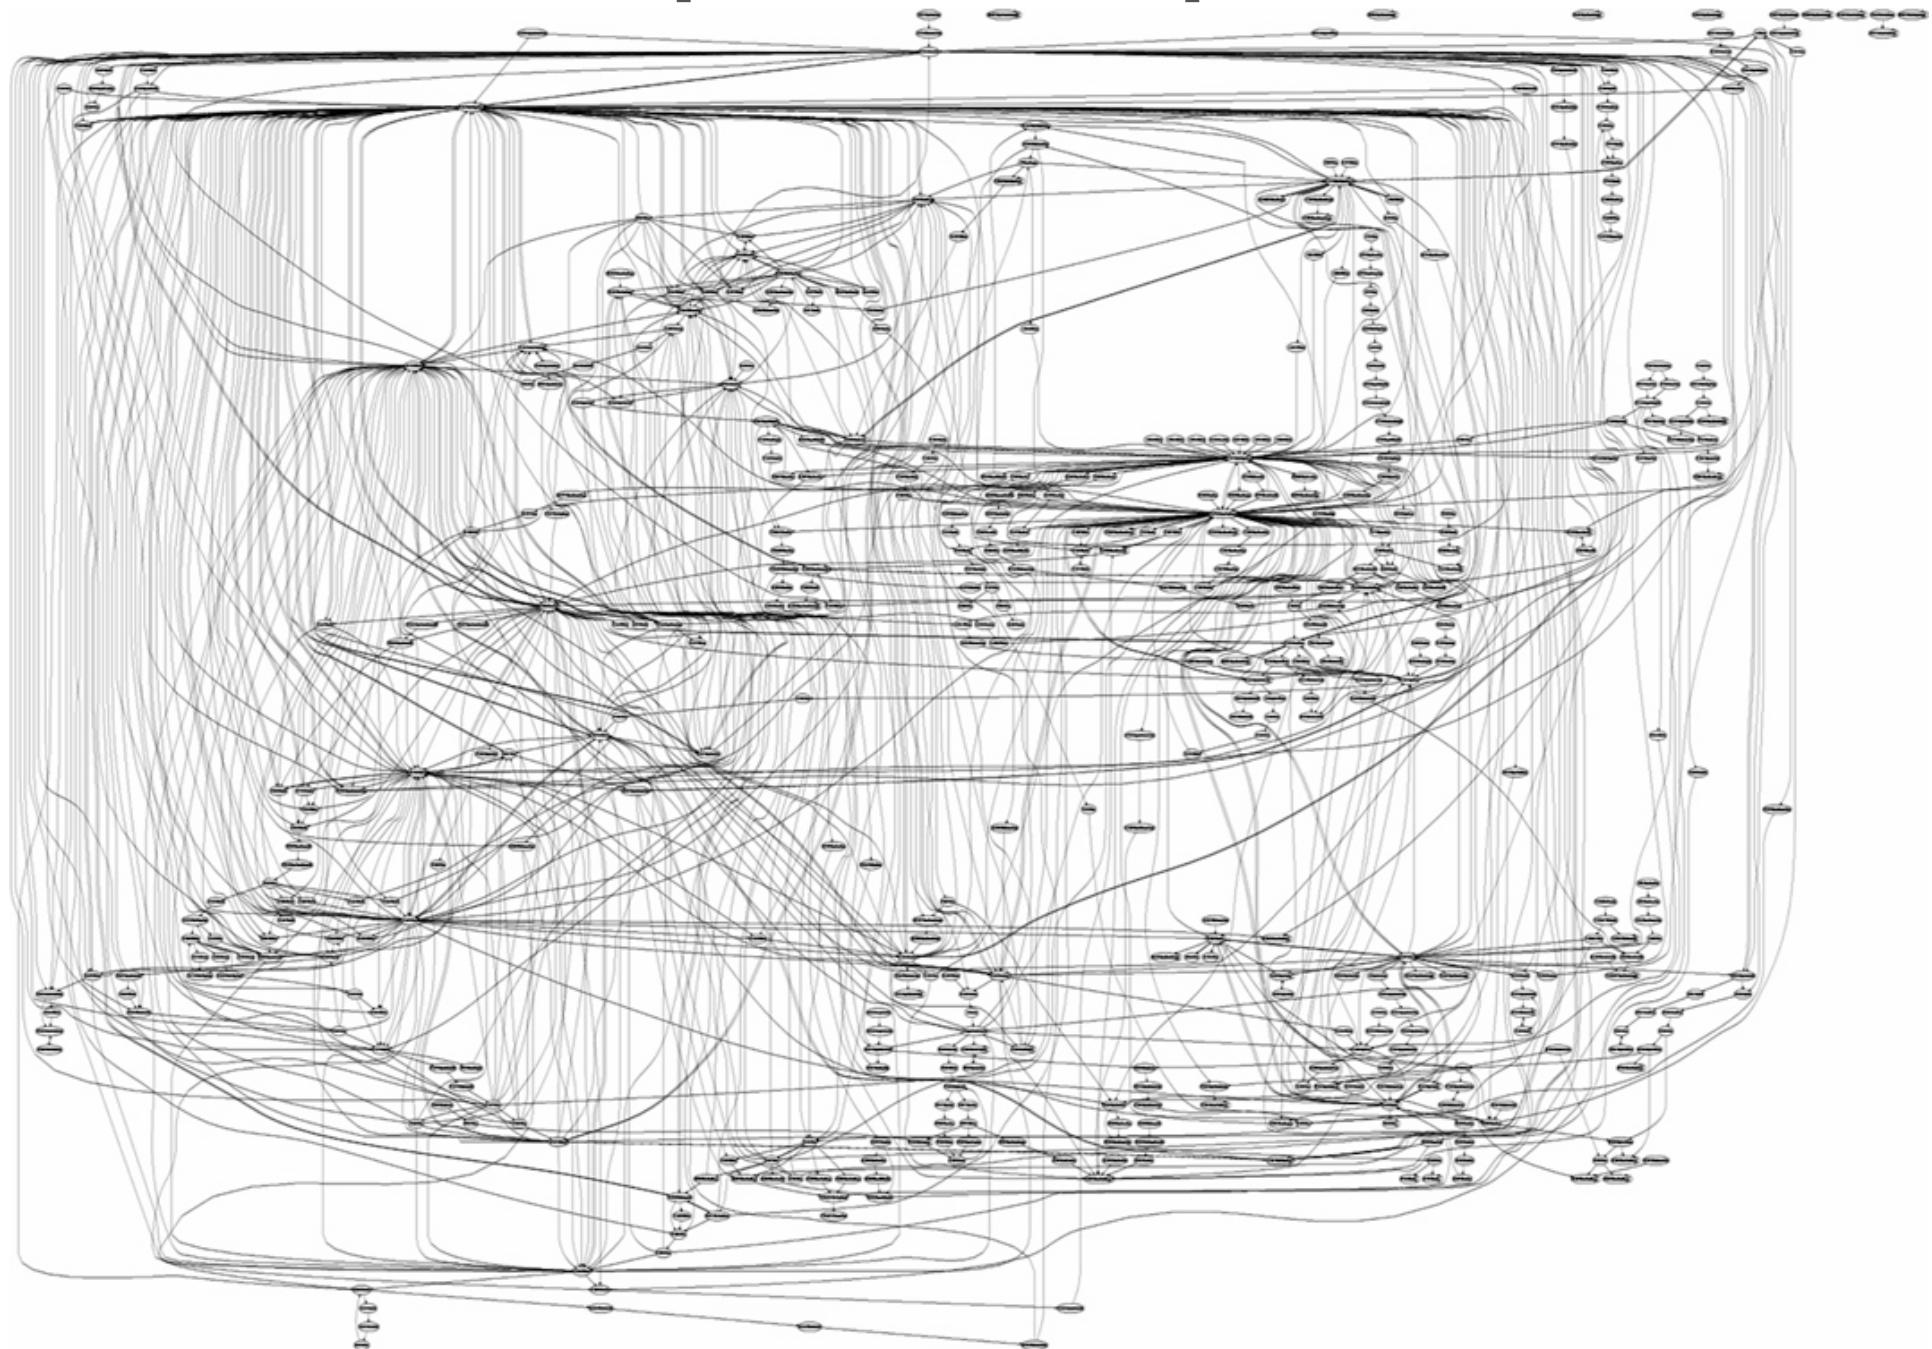

main.c ➔ .

Azureus

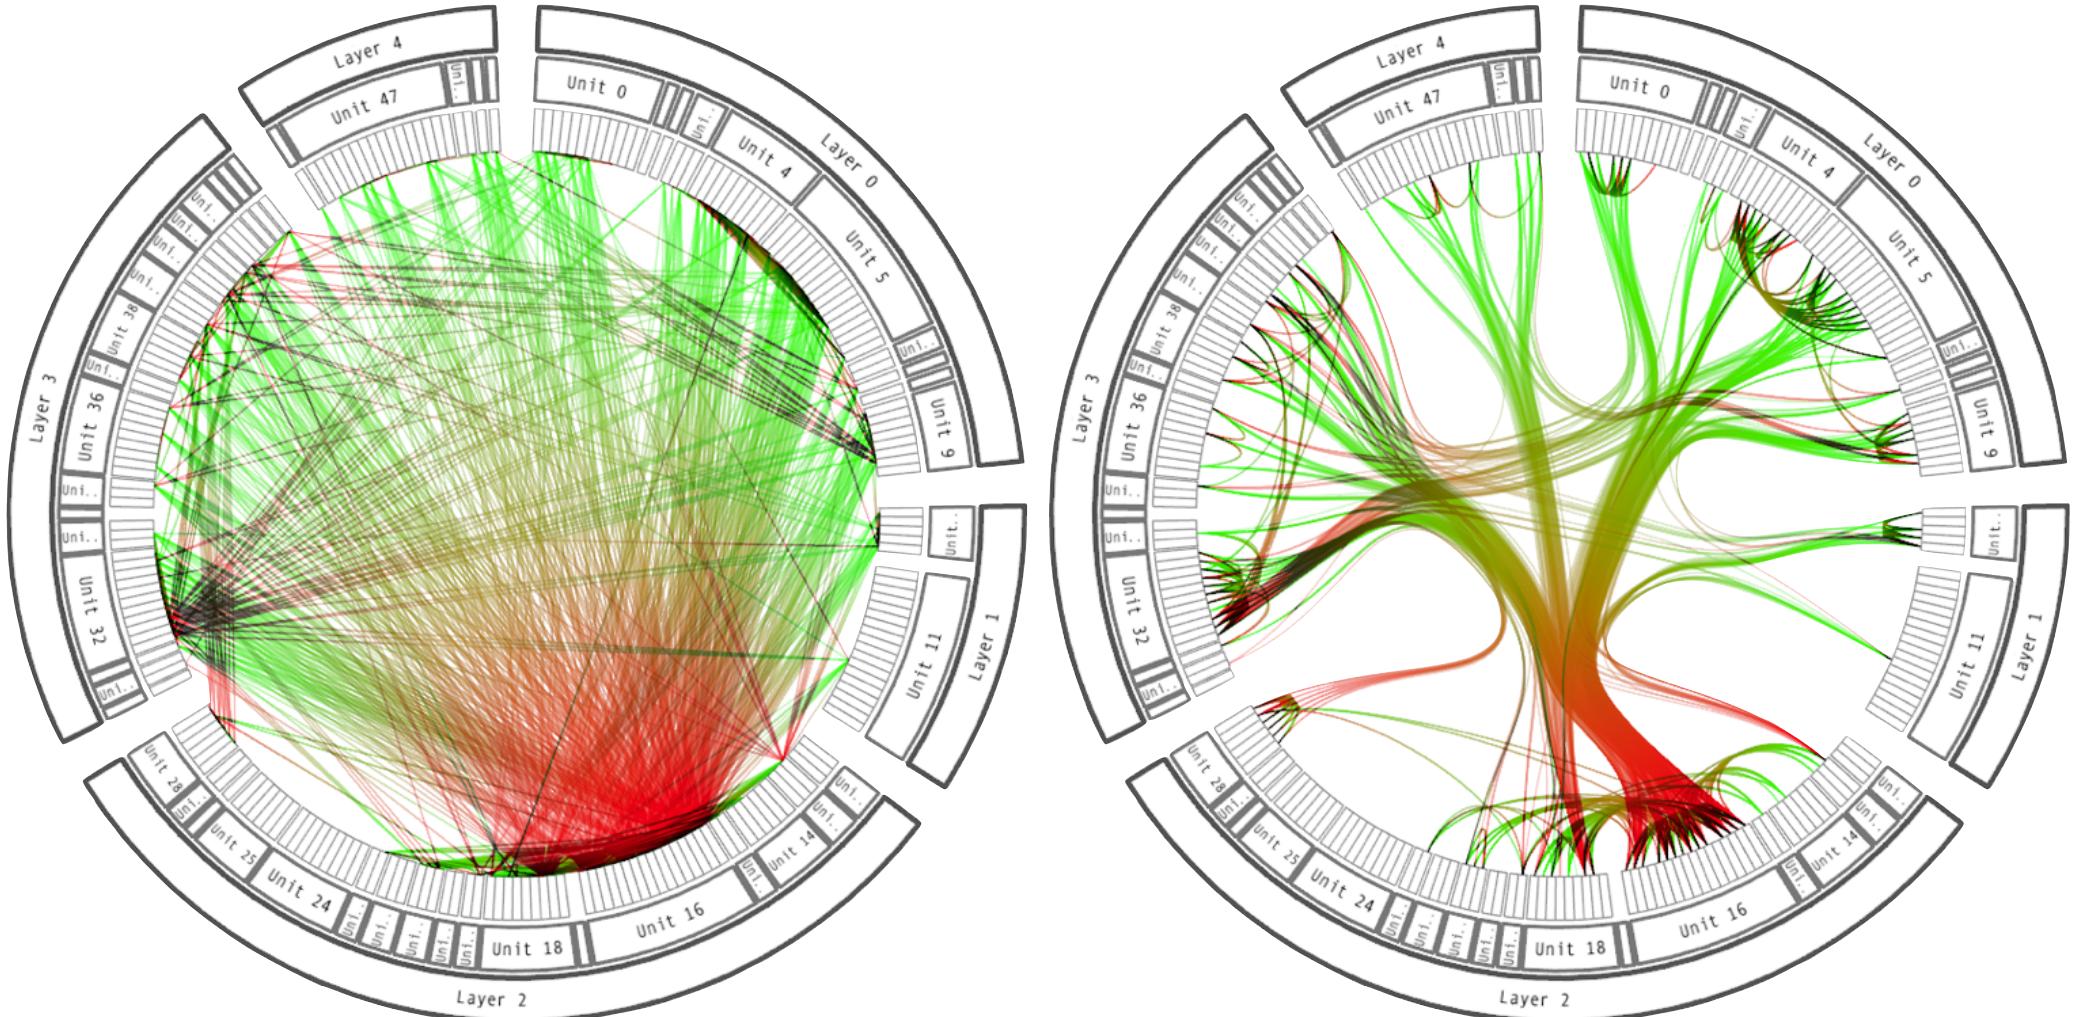

Azureus ➔

Windows

The relationships are complex too!

Software is invisible

There is still a long way to go ...

Software is malleable

It is easy to change software ... too easy?

Ease of change is expected.
Hasty changes hamper maintainability.

Software must **conform** to its domain

Changes in the domain cause changes in the software.
Software engineers must possess some domain knowledge.

Software is discontinuous

People understand linear systems easily.

Some domain aspects: mission-critical vs non-critical software

Software maintenance & evolution

Maintenance & evolution: facts and figures

Lehman's laws of software evolution, first observed on IBM's OS/360

Continuing Change – Software systems must be continually adapted or they become progressively less satisfactory.

Increasing Complexity – As a system evolves, its complexity increases unless work is done to maintain or reduce it.

Self Regulation – The evolution is self regulating with distribution of product and process measures close to normal.

Conservation of Organisational Stability (invariant work rate) - The average effective global activity rate in an evolving system is invariant over product lifetime.

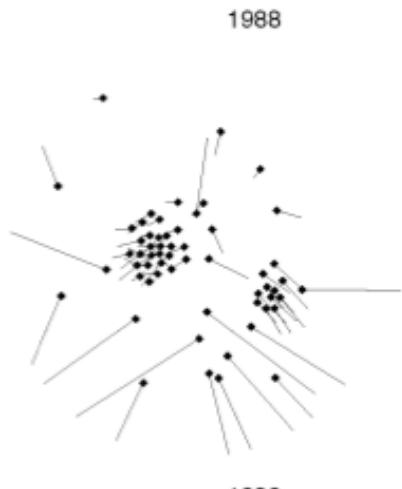

Conservation of Familiarity – As a system evolves, all associated with it, developers, users, ..., must maintain mastery of its content to achieve satisfactory evolution. Excessive growth diminishes that mastery, hence growth is invariant.

Continuing Growth – The functional content of a system must be continually increased to maintain user satisfaction.

Declining Quality – The quality of systems declines unless they are rigorously maintained and adapted to changes.

Feedback System – The evolution processes constitute multi-level, multi-loop, multi-agent feedback systems and must be treated as such to achieve significant improvement over any reasonable base.

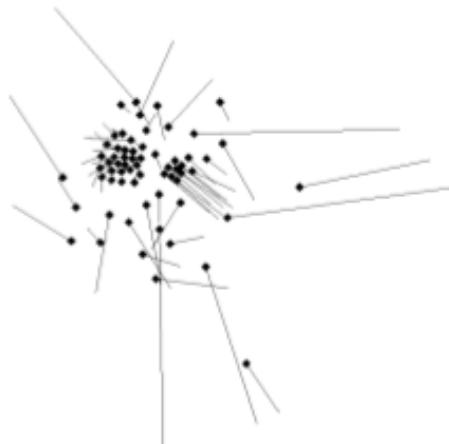

Some visual examples of code decay

Estimates of the cost of software put
maintenance at

90 %

[Erlich, 2000]

40 % or more, according to [Brooks, 1975]

Y2K

Table I
Magnitude of the Y2K Mess

	Number of applications	Applications with Y2K problems (%)	Number of files	Files modified (%)	Screens and reports modified (%)	Hardware upgraded or replaced (%)	System software and utilities upgraded or replaced (%)
Average	1,090	65	9,900	33	31	27	49
Median	163	75	2,500	20	20	15	38

“I had the opportunity to track the progress and practices of hundreds of Y2K projects since 1996. [...] On average, these projects consumed more than 50% of one year’s IS operating budget. This puts Y2K’s total global cost between \$375 and \$750 billion. [...] About 45% of all applications were modified because of Y2K and another 20% replaced entirely.”

[Kappelman, 2000]

Some other studies:

60%

of the time is spent **understanding** existing code

[Corbi, 1989]

40%

of bug fixes introduce **new** bugs

[Purushotaman and Perry, 2005]

20 to 50%, according to [Brooks, 1975]

Definition of a maintenance programmer

A programmer whose job mainly consists of changing code that someone else has written.

Categories of software maintenance

Perfective: introduce new functionality in the system

Adaptive: adapt the system to new circumstances (new OS, etc)

Corrective: fix software defects

Preventive: in prevision of future changes (refactorings, etc)

More than half of the changes are perfective. Introducing new functionality is also called software **evolution**.

[Swanson, 1975]

Categories of changes, by impact on functionality

Incremental changes: add new functionality, increase value.

Contraction changes (code pruning): remove obsolete functionality; no increase in value, but reduces bloat.

Replacement changes: replace a functionality with a newer one (bug fix); often an incremental change as well.

Refactoring: no change in functionality, but structural improvement; no increase in value, but increases maintainability.

Categories of changes, by impact on the system

Localized changes: Impact a single or few modules
(small bug fixes, change anticipated in the design)

Non-localized changes: Impacts a dozen (or more) modules
(significant new functionality)

Massively delocalized changes: Impacts a large part of the system
(fundamental design change, changes in the OS, Y2K)

Change strategies

“Quick fixes” done in urgency degrade the structure (copy-paste, etc...), and have long-term costs.

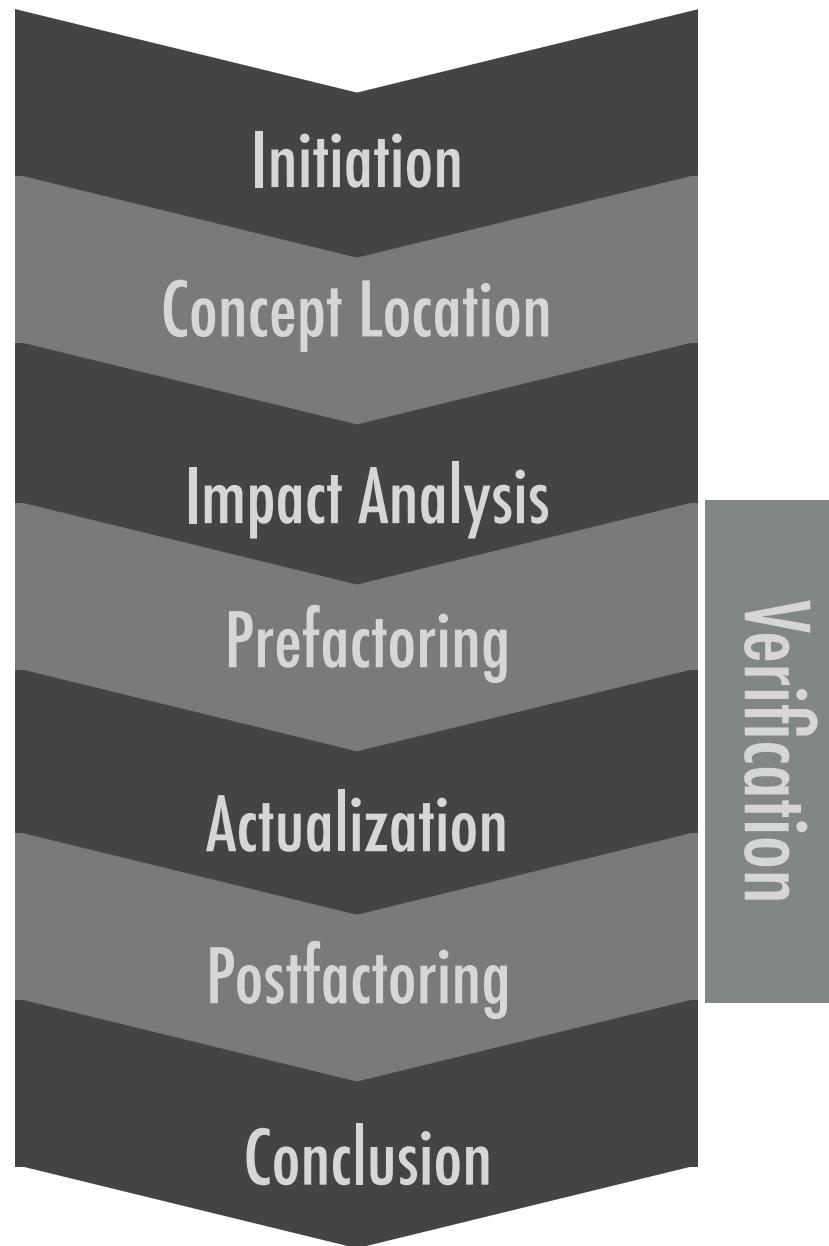

Changes should be well-designed and improve (through refactoring), rather than degrade, the structure of the software.

The software change process

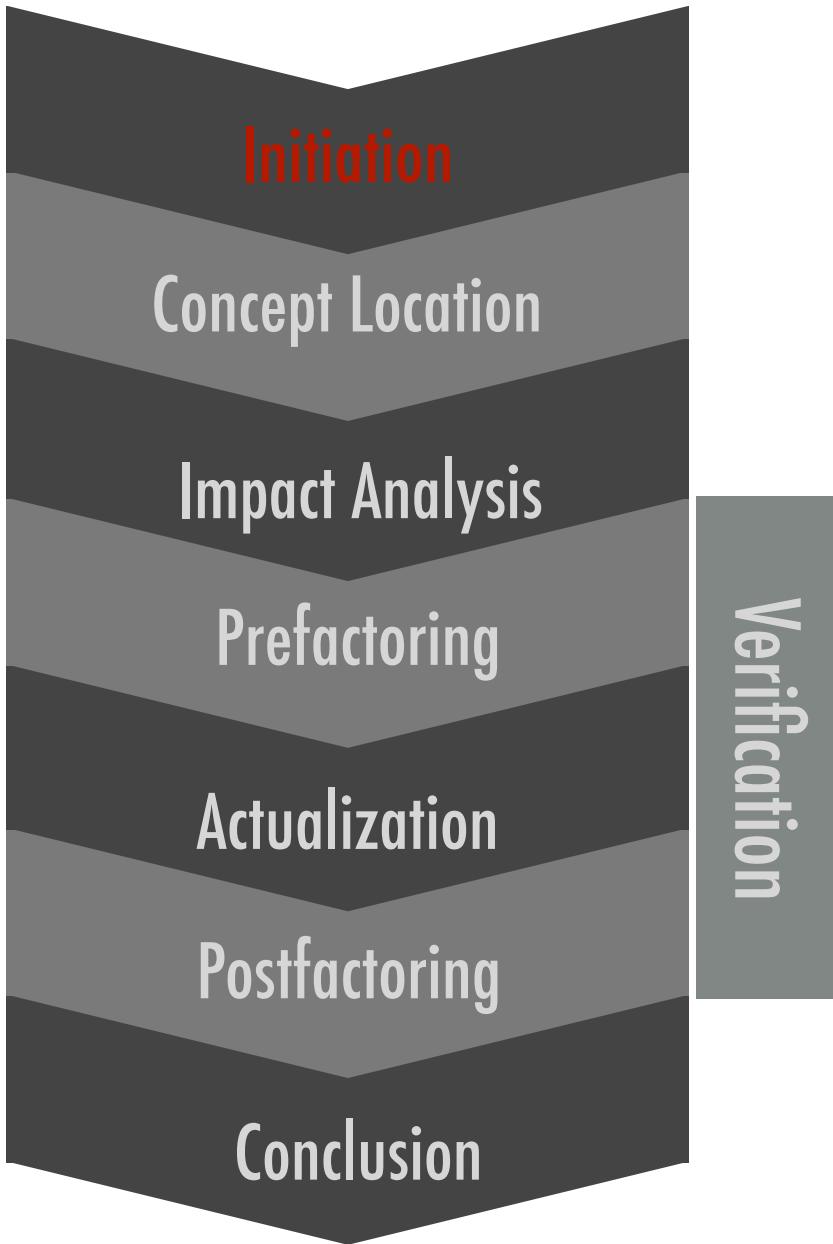

**Unlike design, maintenance work is on
the actual software**

We need a process that works even if the quality of the code is not optimal

A typical software change process

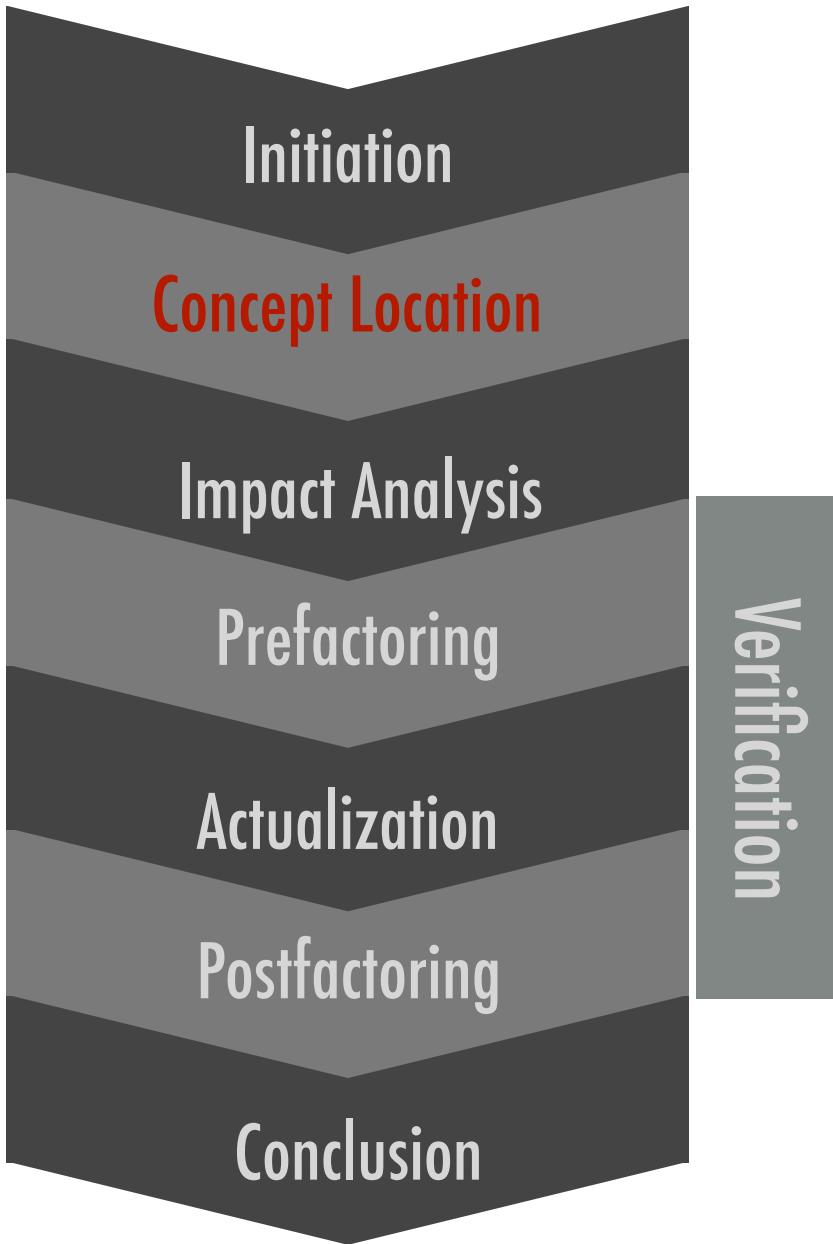

Initiation marks the start of the process

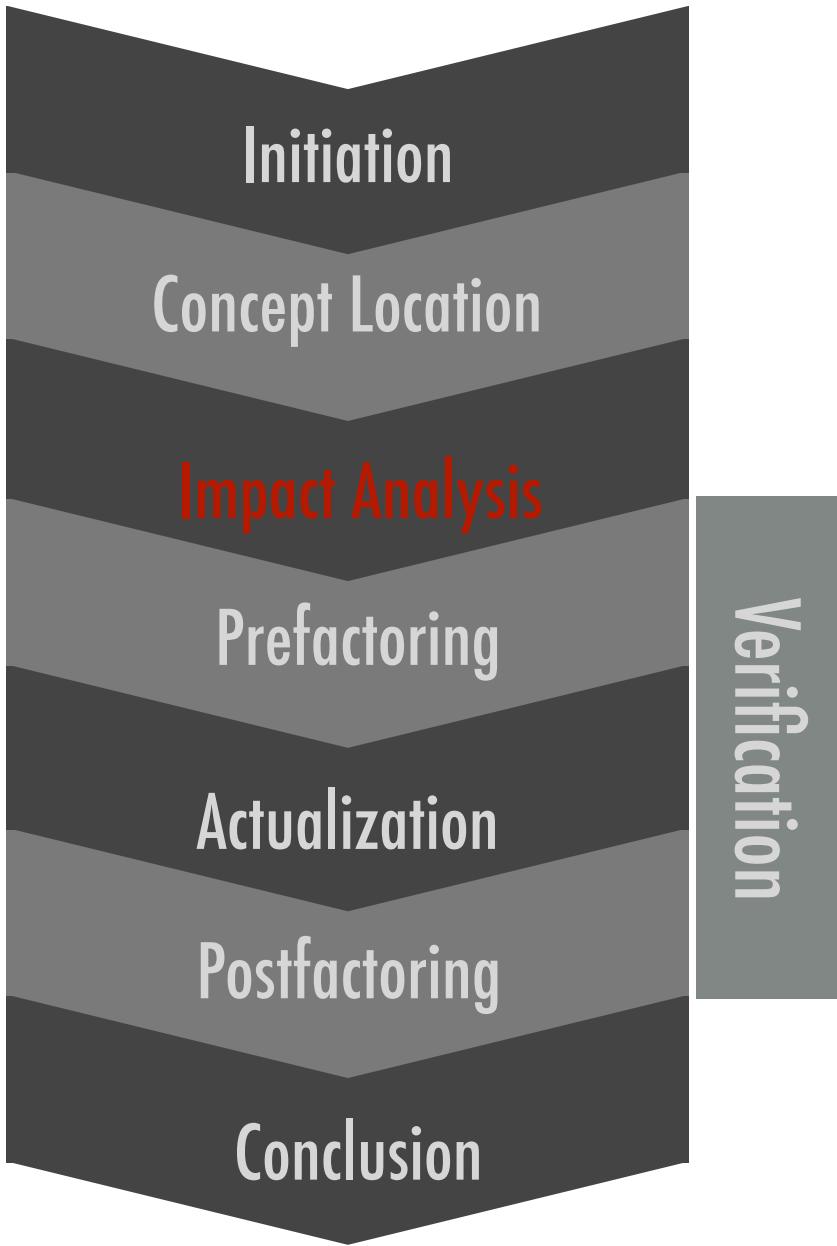

A new change request arrives,
or is selected from the
product backlog

Concept location finds a starting point

The programmer looks for the module that needs to be changed to implement the change request

Impact analysis estimates actual changes

If the change is not localized, the programmer determines which other modules are affected by the change.

Then the change is implemented

The programmer decides of a strategy for the change and changes the source code

Actualization adds new functionality

The programmer updates modules, adds new modules, and propagate changes to affected modules identified by IA.

Refactoring improves the structure of code

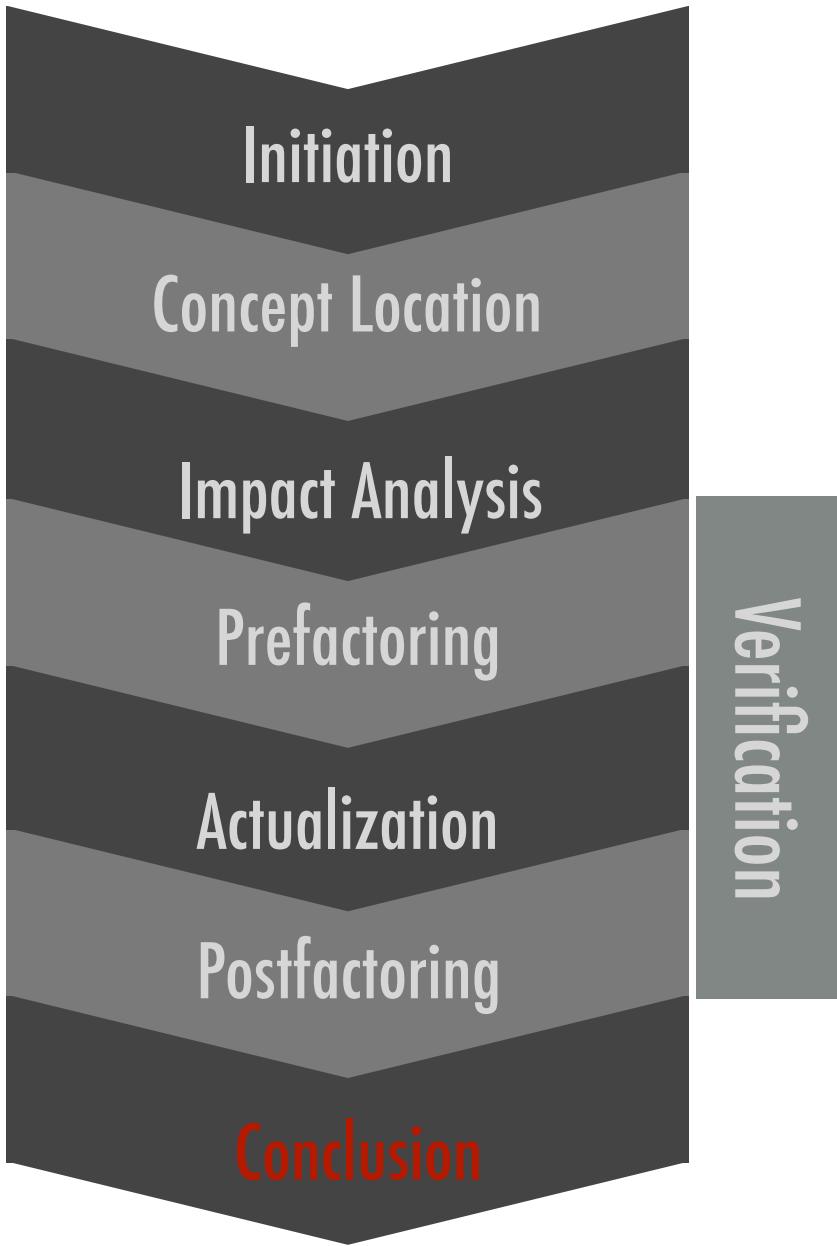

The programmer makes the necessary changes to make actualization easier (prefactoring), and to prevent the decay caused by the change (postfactoring).

Verification ensures changes are correct

The programmer tests that the new functionality works correctly, **and** that the old functionality still works too!

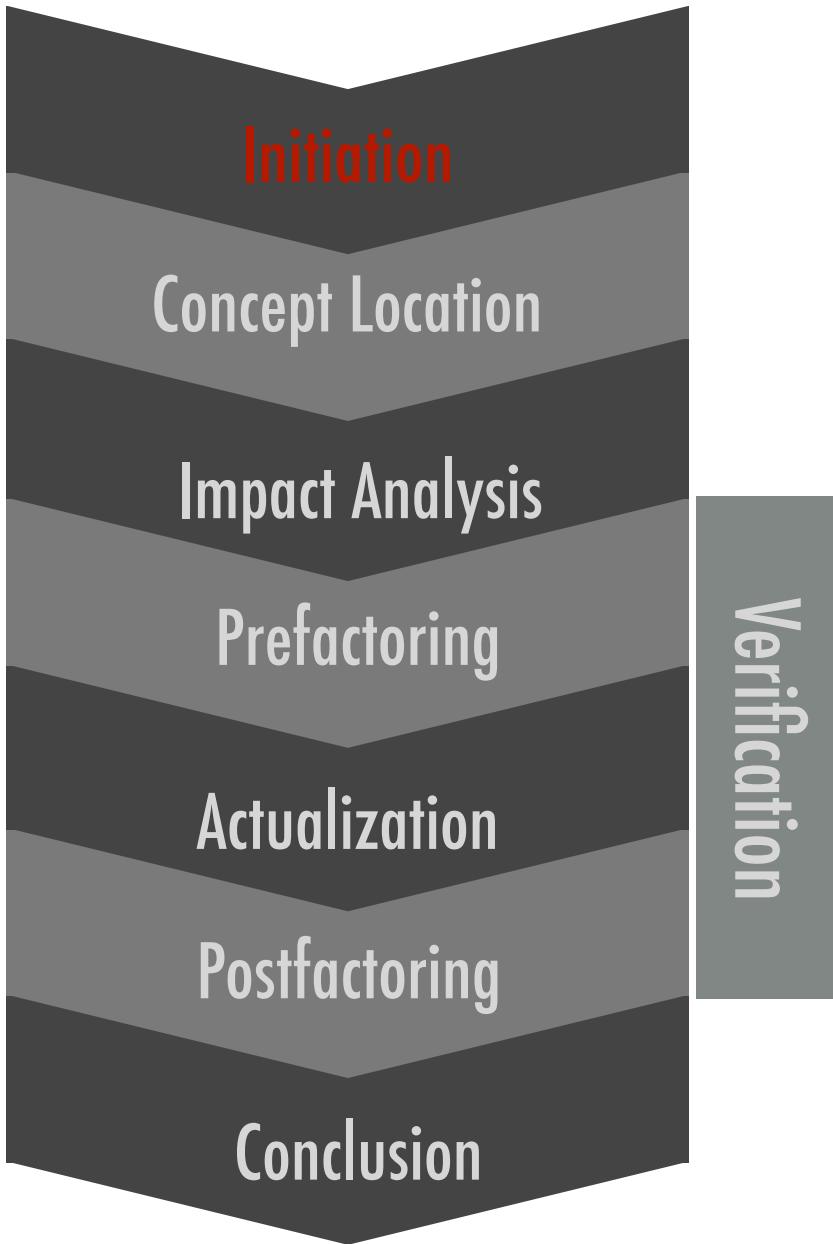

Conclusion updates the project

The programmer commits the changes, creates a new baseline, updates the documentation.

Change initiation

Initiation marks the start of the process

A new change request arrives, or is selected from the product backlog.

What constitutes a change request?

- Change in requirements
- Bug reports
- Competing functionality
- Preventive refactorings
- ...

New functionality can be described in plain english, use cases, user stories ...

Large functionality should be split in several requests.
Change requests are managed in a product backlog.

The product backlog is a queue of requests, sorted by priority

New functionality are sorted by how much value they provide.

Bugs are sorted by their severity:

- Fatal application error (showstopper)
- Serious bug affecting functionality (no workaround)
- Bug affecting functionality (with a workaround)
- Minor issue not involving primary functionality

The first two levels are urgent. The next two are evaluated as any other request.

Expertise is another factor in choosing requests

An expert in the domain or the affected code should be more efficient than a novice.

A cost/benefit analysis can be made (e.g., is this simple to fix for me, and providing enough value?)

The product backlog should be supported by a tool (Bugzilla, Jira, ...)

Statuses of a change request in Bugzilla

Conclusion

Software maintenance & evolution is the costliest phase in the software lifespan

Over time, even the best thought-out design may decay, or be confronted to unanticipated changes (refactoring improves the situation).

Maintainers often have to understand unfamiliar code.

Software maintenance seeks to **keep the complexity under control** in the presence of necessary changes.

Change process supports maintainers

Initiation is the first activity of the process, where a change request is selected for implementation.

We will then talk about the next phases.
